

SOV/136-58-11-9/21

Study of the Behaviour and Recovery of Rhenium in the Roasting of Molybdenite Concentrates in a Fluidized-Bed Roaster

the fluidized roaster, compared with 50% for the rotary kiln but the existing dust-catching system involved 79.5% loss of rhenium in the waste gases. A bubbler (fig.1) installation type VSPU designed by Gintsvetmet which could deal with part of the gas was tested and found to be 89-96% efficient with respect to rhenium, most (75-92%) of the quantity trapped being in the form of soluble compounds; the losses of liquid from the bubbler were shown to be due to evaporation rather than mechanical entrainment. Removal of pulp from the bubbler is recommended when pulp acidity becomes 30-60 g/litre and rhenium concentration 0.15 - 0.30 g/litre. The installation is recommended by the authors. The Mintsvetmetzoloto large laboratory fluidized roaster (fig.2) was used to study the behaviour of rhenium and its recovery in the roasting of low-grade molybdenite concentrates (20.5% Mo, 17.5% S (total), 18.31% SiO₂, 4.06% Cu,

Card 2/3

SOV/136-58-11-9/21

Study of the Behaviour and Recovery of Rhenium in the Roasting of Molybdenite Concentrates in a Fluidized-Red Roaster (1.60% CaO, 7.16% Fe, 0.21% W, 0.04% Re) at 590-630°C and an air velocity in the stack of 8-9 cm/sec (giving an hourly productivity of 75-80 kg/m² of hearth area). A materials balance (table 3) for a 12 hour run shows that the method is successful with such concentrates; the distillation of rhenium being 93.2% of the quantity in the concentrate. There are 2 figures and 3 tables.

TEXT: The authors present the results of their study of: (a) the distribution of Re in the products obtained from roasting Kadzhara molybdenite concentrates in a boiling-layer furnace, (b) the recovery of Re from waste gases of a boiling-layer furnace by means

Card 1/3

Study of the behavior ...

S/697/61/000/000/004/018
D228/D303

as compared with only 50 - 67% in muffle and rotary tubular furna-
 ces. 2) The existing dust-collection system of the boiling-layer
 furnace does not guarantee a satisfactory degree of Re extraction,
 since the loss of metal in waste gases amounts to about 80%. The
 lowering of the temperature of the Cottrell filter to 55 - 80° does
 not reduce this loss on account of the condensation of H₂SO₄. 3)

Much better results can be obtained with the bubbling unit, and the
 bubbler's efficiency with respect to Re is stated to equal 89 - 96%.
 75 - 92% of the metal in the bubbler pulp is in solution, and the
 concentration of dissolved Re rises as the duration of the bubbling
 lengthens. It is recommended that the pulp be removed from the bubb-
 ler when the Re concn. and acidity of the solution is 0.15 - 0.3 and
 30 - 50 g/l respectively. 4) The high degree of Re sublimation (92-
 93.2%) from the ash of Koundrad concentrate shows that the same
 technique can also be applied to this material; there is no diffe-
 rence in the behavior of Re during the roasting of both concentra-
 tes and the processing of their gaseous products in the bubbling
 unit. There are 3 figures and 4 tables. / Abstracter's note: p.48
 of the photostat copy is illegible. /

14K70 (Sb. "Renyi". M., AN SSSR, 1961, 75 - 80)

TEXT: To remove Pb, Sn and other impurities from metallic rhenium it is suggested that the pressed powder be vacuum-heated under a residual pressure of $1 \cdot 10^{-4}$ mm Hg, at a temperature of 2500°C for 2 hrs. The purity of the metal so obtained was 99.988% with respect to 13 impurities (Fe, Al, Mo, Cu, Ni, K, Na, Ca, Pb, Sn, Cd, Bi, Sb). In order to reduce the K and Ca content the metallic Re was produced from ammonium perrhenate. The Re contained 0.02% K and 0.009% Ca. A method is suggested for producing high-purity rhenium containing $<0.0001\%$ of each of the impurities Pb, Sn, Cd, Bi, Se which it is required to limit. [Abstracter's note: Complete trans-
lation.] ✓

TITLE: Examination of solubility in the system potassium perrhenate - potassium chloride - water

PERIODICAL: Zhurnal neorganicheskoy khimii, v. 7, no. 7, 1962, 1670 - 1674

TEXT: Studies of the system $KReO_4 - KCl - H_2O$ at 0, 25, 50, and 75°C showed the solubility isotherms to consist of two branches. The branch which corresponds to the crystallization of potassium perrhenate showed only one solid phase, namely anhydrous $KReO_4$. The very small crystallization branch of KCl was not studied. $KReO_4$ was found to be salted out by KCl, an effect which increases as the temperature is lowered. An addition of 10% by weight of KCl to the solution reduces the solubility of $KReO_4$ at 75°C to 1/5 and at 0°C to 1/32. Complete separation of $KReO_4$ could not be achieved at 75°C. Although the solution was saturated with KCl, it still contained 0.35% of $KReO_4$. At 0°C, the separation of $KReO_4$ was practically

TITLE: Physicochemical principles of the hydrometallurgical method of rhenium refining

SOURCE: Vsesoyuznoye soveshchaniye po probleme reniya. 2d. Moscow, 1962. Rheniy (Rhenium); trudy soveshchaniya. Moscow, Izd-vo Nauka, 1964, 36-39

TOPIC TAGS: rhenium, rhenium refining, hydrometallurgical refining, molybdenum concentrate, calcium molybdate, potassium perhenate

ABSTRACT: The authors studied the system $\text{Ca}(\text{ReO}_4)_2 - \text{CaMoO}_4 - \text{H}_2\text{O}$ at 20 and 75C by the isothermal method for the purpose of elucidating the degree and nature of the trapping of rhenium by the precipitate formed as a result of the neutralization of acidic molybdenum concentrates with calcium oxide. It was found that when molybdenum is precipitated by calcium oxide, rhenium and molybdenum coprecipitate until the latter has completely separated, and rhenium is thought to enter into the crystal lattice of calcium molybdate. After the precipitation of the latter,

Card 1/2

L 23877-65

ACCESSION NR: AT5002754

the trapping of rhenium is due to adsorption processes. The experiments elucidated the general nature of the distribution of rhenium during the precipitation of calcium molybdate. In addition, the authors investigated the conditions of maximum separation of rhenium when it is precipitated in the form of potassium perrhenate by potassium chloride. To this end, they studied the equilibria in the ternary systems $KReO_4 - KCl - H_2O$ at 0, 25, 50, and 75C, and $NH_4ReO_4 - NH_4Cl - H_2O$ at 0, 25, and 75C by the solubility method (under isothermal conditions). On the basis of this investigation, optimum technological conditions were selected for the process of rhenium refining. Orig. art. has: 2 figures.

TITLE: Investigation of cyclic strength of metals by the method of internal friction

SOURCE: Prochnost' metallov pri peremennykh nagruzkakh; materialy* tret'yego soveshchaniya po ustalosti metallov, 1962 g. Moscow, Izd-vo AN SSSR, 1963, 283-289

TOPIC TAGS: cyclic strength, metal strength, metal fatigue, internal friction, fatigue failure, microfissure, metal crystal, microcrack

ABSTRACT: The cyclic strength of metals and the phenomenon of their fatigue failure have been investigated over a period of more than 100 years. As a result, physical evidence has been obtained to construct a general theory of fatigue failure. Although a firmly established point of view does not exist with regard to fatigue failure, at the present time three phases in the formation of a fatigue fracture can be noted. The first phase is connected with the strengthening of crystals unfavorably oriented with respect to the field of acting forces and with the occurrence of subtle sliding in these crystals. In the second phase, loosening begins to take place in some crystallites. The nature of this loosening is thoroughly understood but some authors conceive this loosening takes the form of dispersed ruptures of interatomic ties. Others believe that this loosening results in the

Card 1/4

ACCESSION NR: AT4014056

appearance of microfissures during the second phase. In the third phase, the development of the loosening process results in micro- and macro-cracks of fatigue. The authors have tried to clarify the physical picture of the different phases of fatigue failure, particularly the early stages of this process. Fatigue tests have been made on aluminum (99.98%), cadmium (99.9%), zinc (99.99%), and Cd-Zn alloys (0.5, 2.95, 10, and 17.4% Zn). All test specimens were 100mm long bars of a section $0.4-1\text{mm}^2$, and were annealed before the tests. Internal friction was measured by a device designed on the principle of a torsional pendulum. As a measure of inner friction, the logarithmic decrement divided by π has been used. Zero-to-maximum axial cyclic deformation was imposed by a generator of mechanical oscillations GMK-1, fed by an alternating current from a sound generator GZ-2. Torsional fully reversed loading was imposed by a special device. The influence of cyclic deformation in axial zero-to-maximum tension and in reversed torsion was determined on: (1) the temperature dependence of internal friction; and (2) the internal friction at constant temperature. The influence of intermediate annealing was also determined in some experiments. The rate of change in internal friction and the number of cycles to failure were correlated. In the case of the Cd-Zn alloys, these values were plotted against the zinc content in the alloy. As a result of the investigations it has been noted that, independently of the type of cyclic deformation, its influence noticeably increases the internal friction during the first cyclic range (corresponding to the first phase of the formation of a fatigue

Card 2/4

ACCESSION NR: AT4014056

failure) at low temperatures (20-300C for aluminum), and sharply increases the internal friction at high temperatures (above 0.6 of the melting point). This has been explained by an increase in the number of inner defects in the crystal structure. The increase in internal friction discontinues when the number of defects reaches a maximum value attainable under the given conditions. At this stage the loosening of the metal structure begins, explained by coagulation of vacancies. The resulting formation of micro-pores and micro-fissures does not increase the internal friction, and corresponds to the second phase. During the third phase in which micro-fissures develop into fatigue cracks, the internal friction is slightly increased. The investigations into changes in internal friction of metals under cyclic loading, depend on the number of cycles, test temperature, annealing temperature, and the alloy content, have somewhat clarified the question of the physical character of fatigue failure phases. The observed sensitivity of internal friction to the influence of cyclic deformation proves that subtle physical changes occur during the first phase of fatigue failure. Systematic investigations of $Q^{-1}(N, T)$ should be conducted to discover these changes. It is necessary to continue the study of correlations established by the authors between the rate of change of inner friction and the cyclic strength of metals and alloys. Orig. art. has: 4 figures.

AUTHOR: Postnov, G.A.

TITLE: Wave Propagation in an Isotropic Plasma Waveguide

PERIODICAL: Radiotekhnika i elektronika, 1960, Vol.5, No.10,
pp.1598-1602

TEXT: This article is a theoretical investigation into the propagation of electromagnetic waves in waveguides filled with plasma. The idealization, made in previous literature, that the plasma electron concentration N is uniform over the waveguide cross-section is not assumed. If the plasma is excited by a constant or high-frequency discharge and if, to avoid non-linear effects, the high-frequency energy is small, then a dynamic equilibrium is established in the waveguide between the collision ionization due to the electric field and volume recombination and diffusion at the waveguide walls. The latter reduces the electron concentration at the walls. Since the dielectric permittivity is related to the concentration by the formula

$$\epsilon = 1 - \frac{4\pi e^2 N}{m\omega^2}$$

Card 1/4

21580

S/109/60/005/010/003/031
E033/E415

Wave Propagation in ...

it follows that ϵ is a function of the waveguide coordinates. For an inhomogeneous medium, Maxwell's equations take the form

$$\text{rot } \vec{E} = jk\vec{H}; \quad \text{rot } \vec{H} = -jk\epsilon\vec{E} \quad (\text{assuming } \mu = 1)$$

Substituting one equation in the other,

$$\Delta \vec{E} + k^2 \epsilon \vec{E} - \text{grad div } \vec{E} = 0 \quad (1)$$

From the condition of plasma quasi-neutrality

$$\text{div}(\epsilon \vec{E}) = 0 \quad \text{or} \quad \epsilon \text{div } \vec{E} + \vec{E} \text{ grad } \epsilon = 0$$

and Eq.(1) can be rewritten

$$\Delta \vec{E} + k^2 \epsilon \vec{E} - \text{grad} \left[-\frac{1}{\epsilon} (\vec{E} \text{ grad } \epsilon) \right] = 0. \quad (2)$$

similarly

$$\Delta \vec{H} + k^2 \epsilon \vec{H} + \frac{1}{\epsilon} [\text{grad } \epsilon \text{ rot } \vec{H}] = 0. \quad (3)$$

Card 2/4

21580

Wave Propagation in ...

S/109/60/005/010/003/031
E033/E415

These two equations are then applied to the three following cases and approximate solutions obtained:

1. A flat plasmonic waveguide, i.e. two infinite conducting planes with plasma between them.
2. A cylindrical waveguide with (a) an H_{01} wave and (b) an H_{11} wave.

It is shown that for the flat waveguide, the electric field is a Mathieu function of the first order. Particular values can be found from tables and hence the propagation constant can also be found. The distributions of the electric field across a waveguide section with different values of concentration N are illustrated and it can be seen that, commencing at some particular value of N_0 , a "gap" appears in the field at the centre of the waveguide. The results also show that the phase velocity is less with non-uniform concentration than with uniform concentration. The field in a cylindrical waveguide also has a "gap" in the field at the centre but the phase velocity is greater than in a uniformly filled waveguide. Numerical results for a 3 cm wavelength H_{11} wave in a cylindrical waveguide are tabulated. A general conclusion is that for small values of plasma concentration, the

Card 3/4

21580

Wave Propagation in ...

S/109/60/005/010/003/031
E033/E415

values of the propagation constant agree with those calculated on the assumption of average concentration but with large values of N , when ϵ at the axis becomes zero, the values begin to differ. There are 1 figure, 1 table and 3 Soviet references.

70. Amplified Propagation for "Kobayashi Effect"
The Kobayashi Effect, by N. Kobayashi, Proceedings of the IRE, 1959, p. 1

On 15 November 1959, candidate of technical sciences N. N. KOBAYASHI was presented for the following discovery: "Radiowaves reflected from the ionosphere, upon reaching the earth, partially reflected by the surface, ionosphere, and earth, form a closed energy return to the source of radiation where it may be recorded."

Kobayashi's work lays the basis for the method of "return-oblique ionospheric sounding" (VIZ), which is a new method for studying the ionosphere and radio wave propagation. It will make possible an increase in the stability of radio communications and radio broadcasting by short waves and facilitates rapid and positive communication between all continents.

At the meeting during which Kobayashi received his award, it was pointed out that the ionosphere is a plasma. In 1959, under the leadership of Professor N. N. KOBAYASHI, a group of scientists at the Institute of Acoustic Propagation, Leningrad, S. LUK'YANOV, I. POKROVSKIY, V. SILETSKIY, and N. ZILBERMAN, in the study of high-temperature plasmas, they detected a phenomenon of ionospheric radiation which has been hitherto unknown. This radiation originates in a plasma formed by passing powerful current pulses through discharges.

71. Wave Propagation in Plasma-Filled Waveguide Examined
"Wave Propagation in an Ionospheric Plasma Wave Guide" by G. A. POKROVSKIY, Radio Engng. Electron. Phys., Vol. 7, No. 10, Oct-Nov 1959, 1960

The article examines the question of propagation of electromagnetic waves in a wave guide filled with an isotropic plasma, assuming that the concentration of electrons changes through the cross-section of the wave guide. A rigorous solution is obtained for the case of a flat wave guide; for a cylindrical wave guide, an approximate solution is obtained by two different methods, and results are tabulated.

Results show that for a certain value of electron concentration along the walls, the central region in the wave guide becomes completely reflecting and the ionospheric plasma waveguide is transformed into a closed wave. Propagation of electromagnetic waves in plasmas wave guide continues even at very high electron concentration and when the plasma column completely reflects waves laterally incident on it.

AUTHOR: Postnov, G.A.

TITLE: Conditions of slow wave existence in an isotropic plasma waveguide

PERIODICAL: Radiotekhnika i elektronika, v. 6, no. 8, 1961, 1325 - 1327

TEXT: One method of obtaining a slow wave, i.e. a wave whose number is greater than that of the wave propagated in free space, is by putting a stratified dielectric across the axis of a cylindrical waveguide. The other method of retardation is by filling the waveguide by a gyrotropic plasma; this method requires considerable magnetic fields in the centimeter region making it impracticable. It is possible to retard the wave without the magnetic field by applying the principle of stratification, e.g. by utilizing plasma inhomogeneities. In order to obtain slow waves another surface has to be introduced into the waveguide which would change the electron concentration and consequently change the permittivity of its Card 1/5

24887

S/109/61/006/008/007/018
D207/D304

Conditions of slow wave ...

plasma. In the present article the author solves the problem of such a waveguide. He considers a flat waveguide with plasma (Fig.1) with a thin dielectric membrane equidistant from its walls. If the diaphragm has its permittivity near to unity, then it does not introduce any appreciable distortion of the field and the fall rate of plasma concentration in its vicinity will be practically the same as at the wall. Approximating the distribution N by a cosinusoid

$$N = N_0 \left| \sin \frac{\pi y}{2b} \right| \quad (2)$$

is given where $2b$ is the distance between the walls of the flat waveguide as shown in Fig. 1. After substituting and using the Floquet theorem, the general solution of a Hill equation is

$$E_x = A e^{\mu \zeta} \Phi(\zeta, \sigma) + B e^{-\mu \zeta} \Phi(\zeta, -\sigma),$$

where σ - is a parameter. Function Φ can be represented also as a

Card 2/5

Conditions of slow waves ...

S/109/61/006/008/007/018
D207/D304

trigonometrical series with σ as phase. The boundary conditions require that E_x be an even function, which means that $B = 0$. Using

$$\theta_0 = 1 - \theta_2 - \frac{1}{8} \theta_2^2 - \frac{1}{4} \theta_2 \theta_4 - \frac{1}{8} \theta_4^2 - \dots \quad (6)$$

or substituting the values of coefficients

$$\left(\frac{2b}{\pi}\right)^2 \left[k^2 - h^2 - \frac{4q}{\pi} \right] = 1 - 0,4264q - 0,0783q^2 - 0,0001q^3 - \dots$$

is obtained. The dependence of $(k^2 - h^2)$ on parameter q , at 3 cm wavelength is given with the same dependence shown for a flat waveguide without dielectric. It may be seen that starting with $q = 5.56$ slow waves start to appear in the waveguide which corresponds to the concentration $N_0 = 4.24 \cdot 10^{12} \text{ cm}^{-3}$. The above proof is of interest because Ya. B. Faynberg and N. A. Khizhnyak (Ref. 1: ZhTF, 1955, 25, 4, 711) have proved that when a waveguide is filled

Card 3/5

Conditions of slow wave ...

AUTHORS: Postnov, L. M., and Gulyayev, B. B.

TITLE: Axial shrinkage porosity in the walls of steel castings

PERIODICAL: Referativnyy zhurnal, Mashinostroyeniye, no. 3, 1961, 21, abstract 3G179. (V sb. "Usadochn. protsessy v metallakh". Moscow, AN SSSR, 1960, 74-84)

TEXT: The authors give a brief description of the kinds of porosity depending on the formation conditions: dispersed, axial and local porosity. The process of formation of axial shrinkage porosity is investigated, which is the main cause of a decrease in mechanical properties of the metal in the casting walls. When the limit of metal consumption through the wall cross section becomes less than the consumption determined by the shrinkage conditions, the continuity of the flow is changed by local metal displacements. The advent of this moment determines the general density of the casting. A mathematical analysis of the phenomena based on the thermal laws of solidification and filtration theory, confirmed by a great number of experiments whose results have been worked out by methods of mathematical statistics, make it possible to obtain

Study. Nauchno-issledovatel'skaya konferentsiya po primeneniyu radioaktivnykh izotopov v mashinostroyeniye i izobrazhenii v mashinostroyeniye. Sbornik 1 nauka Moscow, 1957. 4,500 copies printed.

Sponsoring Agencies: UZNA, Glavnoye upravleniye po ispol'stvovaniyu atomnoy energii, and Akademiya nauk SSSR.

Editorial Board of Set: V.I. Dikshin, Academician (Resp. Ed.), M.M. Shumilovskiy (Deputy Resp. Ed.), Yu. S. Zaslavskiy (Deputy Resp. Ed.), L.I. Tatchenko, S.I. Verkhovskiy, S.T. Mararov, L.I. Petrukhin and M.G. Zeleninskaya (Secretary).

Ed. of Publishing House: P.M. Belyumin; Tech. Ed.: P.P. Polonova. FOREWORD: This book is intended for specialists in the field of machine and instrument manufacture who use radioactive isotopes in the study of materials and processes.

COVERAGE: This collection of papers covers a very wide field of the utilization of tracers in industrial research and control techniques. The topic of this volume is the use of radioisotopes in the machine and instrument-making industry. The individual papers discuss the applications of radioisotope techniques in the study of metals and alloys, problems of radioisotope production, metal cutting, engine performance, and defects in metals. Several papers are devoted to the use of radioisotopes in automation of industrial processes, recording and measuring devices, automatic control, flowmeters, level gauges, safety devices, radiometers, Soviet institutes and laboratories. They were published as transactions of the All-Union Conference on the Use of Radioactive and Tracer Isotopes and Methods of Their Application in Machine and Science, April 12-15, 1957. No personalities are mentioned. References are given at the end of the papers.

TITLE:

Investigations of the Effect of Metal Solidification During the Mold Filling Process on the Quality of Steel Castings

PERIODICAL:

V sb.: Zatverdevaniye metallov. Moscow, Mashgiz, 1958, pp 374 - 396

ABSTRACT:

Owing to the heating effects of the flow of overheated metal the solidification of castings in the zones (Z) near the gate is taking place more slowly; even the smelting of the solid skin, forming at the beginning, might occur. These Z solidified late might even get isolated from the supply sources (gate systems, heads) and therefore develop into Z of the greatest shrinkage porosity. Investigations were carried out for a quantitative analysis of the mentioned phenomena as applied to plate castings of carbon steel. The rated formulae are derived and the results of the tests for the determination of the duration of the solidification process and the density of the castings in the Z near the gates are stated. Particularly the distribution of the density and σ_b over the length of plates with dimensions of 1,100 · 325 mm and thicknesses of 10, 20, 30,

and 50 mm, cast in vertical and horizontal positions, was determined. Besides, in these tests the temperature and speed of casting, the quantity of metal which was poured through the gates (for this the number of gates and the size of the heads were varied) and the relative layout of gate and heads were varied. The density was determined by X-ray and gravimetric analysis of cut-out templets. A decrease in density was always accompanied by a corresponding reduction of σ_b . With horizontal casting the Z of porosity was more extensive than with vertical casting, e.g. for a cast plate of 30 mm thickness the porosity zone started at a distance of 60 - 80 mm from the gate and spread out over the length of the plate up to 200 - 300 mm. The contour of the porosity Z corresponds to the shape of the flow when flowing out under a submerged level (the Z expands in the shape of a fan in direction from the gate). A rise of the temperature of the metal and an increase in its quantity, poured through the gate, leads to a considerable reduction of the density of the casting in the Z near the gate. The effects of the casting speed and the thickness of the casting are slight. Based on the investigations, practical recommendations for avoiding the porosity in steel castings in the Z near the gate are

given: casting in a vertical position, dispersed metal supply, adjustment of the heads above the gates (or at least at no greater distance than 2-3 times wall thickness), casting temperature as low as possible. 22 figures.
